

The covering block comprises placed in normal positions frame and under-frame elements arranged of trussed beams with several box-like in profile stands. To decrease deformability of the block and to increase its rigidity, the near frame elements are arranged as being mirror-shaped one with respect to another, and all the stands of those elements, except of the middle ones, are at beneath connected to each other. At that, the vertical links of the block are placed at the middle of the frame structures between each pair of those, and the stands of the under-frame elements, except of the middle one, are connected at beneath to the nearest stand of the frame element. All the stands of the under-frame element are at beneath connected to each other. The slant of the covering in four directions is arranged to the center of the block where the water-receiving funnel is placed.
