

The device for the therapy is designed as a vessel with an extended semicircular bottom and an external opening with thickened smooth edges. The space between the walls filled with the liquid medicinal substance is open inside the vessel via the capillary channel. The device allows the liquid medicinal substances such as the essential oils to be applied onto the skin subjected to hyperemia. Slight modification is sufficient for the device equipped with the air-pipe connected with the compressor to be employed as the accessory for the vacuum massage.
