

The invention relates to agriculture and forestry, namely to methods of forest amelioration of stony steep slopes and can be applied in the protective afforestation. A method of forest amelioration of stony steep slopes includes carrying out band tillage across the slope allowing setting up collecting ditches and planting crops thereon. After the band tillage picking up stones and placing thereof into a continuous dike along the lower border of the band are carried out, and then a collecting ditch is cut above thereof and forest cultures are planted into the wet slope of the established raised dike. The ditch is filled with stones.
