

An invention relates to the oil-gas producing techniques, especially to the circulation valves, designated for connecting and delimitating the internal space of the lift column and the external space while developing and muffling a well, equipped by a packer. In order to solve the task presented in the valve proposed, containing a controlling device, driven by the pressure between the pipe internal space and the pressure in the external space difference, there is an unit for emergency valve opening, switching on after the accessing pressure appears. It does not produce a depression on the productive seams. A leak-proofness of the valve mobile parts increased by usage in the valve structure the self-sealing blocks of the chevron fluoroplastic rings. The relief valve is made as the check valve, and it presents a possibility to reliably block the liquid leakage in one direction.
