

In order to provide a package which is inexpensive to manufacture, sufficiently stable to protect the contents of the package and repeatedly and consistently openable and closeable, a package and a blank therefore is suggested, comprising front wall (10), back wall (14) and side wall. (12) segments, the front and the back wall segments extending into congruent closure segments (20, 24, 32, 28), wherein at least two (24, 28) of the closure segments are arranged to be foldable on top of one another to form a pocket with one open side (26) , and at least a further one of the closure segments (20) is arranged to be insertable into the pocket from the open side thereof in such a manner as to permit repeatable opening and closing of an end of the package.
