

Method for cleaning and distant air sampling at making lift workings comprises of operations of cleaning and distant sampling at the critical area of formation through feeding working medium to the ejectors of cleaning blocks and distant sampling, with formation of the working medium flow of the air and water mains. To provide different combinations of interconnections of executive elements in the lift working additional levels are defined, at that cleaning and distant air sampling at the level of critical area and at additional levels are performed simultaneously; and formation of direction of working medium flow and its supply are changed depending on mode of works implementation at the lift working arrangement. Appliance for implementation of the method - the ejector of cleaning block and ejector of distant sampling, where each of those comprises housing with central nozzle, direct flow, air and water branch pipes, confuser, mixing chamber and diffuser. To expand functional possibilities the ejector of cleaning block is made two-stage, with the second stage formed by elongation of the housing of the first stage ejector that is rigidly connected to sedimentation flexible hose; in the housing there is a perforated section.
