

A method for descending the cargos and the persons from the high-rise objects contains two flexible bearing members interconnected with the connection ties. The free end of the second flexible bearing member is attached at the point when the descent should begin. The object is suspended at the free end of the first flexible bearing member. The breaking load is applied to several connection ties, and the object is descended. The flexible bearing members are interconnected with the resilient connection ties generating the longitudinal gap of the constant size with the suture in parallel to each flexible bearing member. All the resilient connection ties are located in the same plane. The free end of the first flexible bearing member is moved along the surface of the second one.
