

The method to search and retrieve information from various databases included the transmission of search requests into the server search engine with subsequent processing of those requests. In this case, first create users on the system server accounts. At the same time their personal data are imposed and get passwords. Then with a computer user enters a query to the server system to obtain information about the object. Then, the server systems form the automated requests for information about the object of the search. After that, requests are processed on the server system and form information files. Formed files transfer from a server system for reading to users' computer.
